

Neural Net Based Stranger Pairing

I'd like to investigate the possibility of a side-project to implement a neural network based stranger pairing system.

Stranger pairing here means choosing the best pairing of strangers to a players party during combat. The inputs to the neural network would be as follows:

- the party members of strangers
- the artifacts available to the strangers
- the party members of the player
- the artifacts being wielded by the player's party members

Initially, I'm interested in what software is available in the open source domain to allow a neural network to be trained, and then used by the game. Ideally, initially, I'd like to train the network on my MacBook, and then provide it as a service on a linux machine accessible to convex - unless there is a simpler solution.

Create a feasibility document. Assume that I know nothing about training or using custom AI models, but do have a general understanding on how they work.
